

Caregiver Booking System — Requirements & Workflows

2026-09-17 · @Someone

Overview & Scope

This document breaks down the requirements for a **Caregiver Booking System** — a short, focused platform for the admin team to manage patient requests, caregiver bookings, onboarding, and reporting, with WhatsApp and website intake channels.

Assumptions made for this draft:

- "No third-party integration for the website" is read as: the website's request form and WhatsApp click-to-chat button feed directly into our own system (no third-party form builders/chat widgets), while WhatsApp itself is used via its standard Business API — not a layered third-party chat platform.
- Payment is **demo/UI-only**: the system shows a payment link/screen and a "mark as paid" status, with no live payment gateway (Stripe/PayPal/FPX/etc.) wired in for this phase.
- "Gender based" is read as a matching filter (patient can request a male/female caregiver), not a hard system restriction.

Core capabilities in scope:

1. Patient request intake (via WhatsApp and website) → admin-managed booking
2. Caregiver onboarding (self-request → admin approval)
3. Booking/matching engine (availability, location, gender)
4. Admin & management dashboard (bookings, revenue, free caregivers)
5. Audit trail
6. Branding (logo, Malaysia team identity)
7. WhatsApp integration
8. Website integration
9. Payment (demo screen only)

Module 1 — Patient Request Intake & Booking

Purpose: capture a patient's request (from WhatsApp or website) and let the admin turn it into a confirmed booking.

Requirements:

- Central **Requests** queue showing all incoming requests, tagged by source (WhatsApp / Website), with status (New / In Review / Booked / Rejected).
- Each request captures: patient name, contact number, address/location, care type needed, preferred date/time, preferred caregiver gender, special notes.
- Admin can search/filter available caregivers by:
 - **Location** (nearest to patient, by area/zone or radius)
 - **Availability** (free on the requested date/time — no clash with existing bookings)
 - **Gender** (matching patient's preference)
 - Optionally: skill/specialization (e.g. elderly care, post-surgery, pediatric)
- Admin selects a caregiver from the filtered/available list and confirms the booking.
- Booking record stores: patient, caregiver, date/time, duration, location, service type, status, price/rate.
- Patient and caregiver both notified of the confirmed booking (via WhatsApp message and/or system notification).
- Booking can be rescheduled or cancelled by admin, with reason captured.

Module 2 — Caregiver Onboarding

Purpose: let new caregivers apply and let the admin vet and activate them.

Requirements:

- Caregiver applies via a simple intake form (from WhatsApp link or website), or admin manually adds them.
- Application captures: name, gender, contact, location/coverage area, ID/certification documents (upload), skills/specialization, languages spoken, years of experience, availability (days/hours).
- Applications land in an **Onboarding queue** for admin review: Pending → Approved / Rejected.
- On approval, caregiver becomes visible/searchable in the booking engine (Module 1) as "Active."

- Admin can deactivate/suspend a caregiver at any time (e.g. on leave, offboarded), removing them from the available pool without deleting their record.
- Caregiver profile page: personal details, documents, rating/history of completed bookings, current status.

Module 3 — Admin & Management Dashboard

Purpose: give admin and management a single view of operational and business health.

Requirements:

- **Bookings overview:** total bookings (today/week/month), by status (upcoming, in-progress, completed, cancelled).
- **Revenue overview:** revenue generated (today/week/month/custom range), broken down by service type and/or caregiver, outstanding vs. collected payments.
- **Caregiver availability:** count of caregivers currently free vs. assigned vs. inactive, filterable by location/gender/skill.
- **Onboarding pipeline:** count of pending caregiver applications awaiting review.
- **Source breakdown:** requests received via WhatsApp vs. website.
- Charts/graphs for trends (bookings over time, revenue over time).
- Role-based access: Admin (day-to-day operations) vs. Management (read-only reporting view), if needed.
- Exportable reports (CSV/PDF) for management review.

Module 4 — Audit Trail

Purpose: a traceable, tamper-evident log of who did what, for accountability and dispute resolution.

Requirements:

- Every key action is logged: request received, booking created/modified/cancelled, caregiver onboarded/approved/rejected/deactivated, payment status changed, dashboard data exported.
- Each log entry captures: timestamp, actor (admin user), action type, affected record (patient/caregiver/booking ID), before/after values where relevant.
- Audit log is searchable/filterable by date range, actor, action type, or record.

- Log entries are read-only (cannot be edited or deleted by admins) to preserve integrity.
- Accessible to management for review; optionally exportable for compliance purposes.

Module 5 — Branding & Malaysia Team Alignment

Requirements:

- Company logo displayed in the system header/login screen and on any patient/caregiver-facing screens (WhatsApp message templates, payment screen, booking confirmations).
- Malaysia-specific configuration: local timezone (MYT), currency (MYR), local phone number format, and service areas/zones relevant to the Malaysia team.
- Team members and their roles (admin, ops) set up in the system so bookings, onboarding approvals, and audit entries are attributed to the right person.

Module 6 — WhatsApp Integration

Purpose: most patient requests arrive via WhatsApp today — bring that channel directly into the system instead of the admin manually re-typing requests.

Requirements:

- Connect to **WhatsApp Business API** (via Meta's official API or an approved BSP) so incoming messages to the business number are received by the system.
- Incoming WhatsApp messages create/update a request in the Requests queue (Module 1), preserving the conversation so admin has context.
- Structured intake option: a WhatsApp "quick reply" flow or template form (name, location, care type, preferred date, gender preference) so requests arrive structured rather than free text, reducing manual admin re-entry.
- Outbound WhatsApp messages from the system: booking confirmations, caregiver assignment notice, reminders, and (later) payment link.
- Admin can view/reply to WhatsApp threads from within the system (or at minimum, see the full message history tied to each request).

Module 7 — Website Integration

Purpose: requests submitted on the existing website should flow straight into the same system as WhatsApp requests — no manual copy-paste, no third-party form tool in between.

Requirements:

- A **request form** embedded on the existing website (built to match site branding), submitting directly to the caregiver system's API/backend — not routed through a third-party form service.
- A **"Chat on WhatsApp"** button/widget on the website that opens WhatsApp with a pre-filled message, so website visitors who prefer WhatsApp land in the same intake flow as Module 6.
- Website submissions appear in the same Requests queue (Module 1), tagged "Source: Website," alongside WhatsApp-sourced requests.
- Confirmation shown to the website visitor after submission (e.g. "Request received, our team will contact you shortly").

Module 8 — Payment (Demo Scope)

Purpose: show the intended payment flow without wiring up a live gateway — sufficient for the demo.

Requirements:

- Once a caregiver marks a booking "Service Completed," the system generates a **payment screen/link** (mock — no real gateway call).
- Payment screen shows: amount due, service summary, patient details, and a "Pay Now" button (non-functional for demo, or simulates success).
- Admin/caregiver can alternatively mark the booking as **"Paid — Collected Directly"** for cash/direct payments.
- Booking record reflects payment status: Unpaid / Link Sent / Paid, feeding into the revenue figures on the dashboard (Module 3).
- Noted for a later phase (post-demo): real gateway integration (e.g. FPX, GrabPay, card) — out of scope for now.

End-to-End Workflows

Workflow 1 — Patient Request via WhatsApp

1. Patient messages the business WhatsApp number.
2. System receives the message via WhatsApp Business API, creates a new **Request** (Source: WhatsApp), status "New."
3. If structured flow is used, patient is guided through quick-reply questions (location, care type, date/time, gender preference); otherwise admin fills these in from the free-text chat.
4. Request appears in admin's Requests queue.

Workflow 2 — Patient Request via Website

1. Visitor fills the request form on the website (or clicks the WhatsApp button, which routes into Workflow 1).
2. Form submits directly to the system backend, creating a new **Request** (Source: Website), status "New."
3. Visitor sees an on-screen confirmation.
4. Request appears in admin's Requests queue, same as Workflow 1.

Workflow 3 — Caregiver Booking / Matching

1. Admin opens a "New" request.
2. Admin runs the matching filter: location, availability on requested date/time, gender preference (+ skill, if used).
3. System returns a list of eligible, currently-free caregivers.
4. Admin selects a caregiver and confirms the booking.
5. Booking record created (status "Confirmed"); request status updates to "Booked."
6. System sends confirmation to patient and caregiver via WhatsApp.
7. Audit log entry created ("Booking created by [admin], caregiver [X] assigned to patient [Y]").

Workflow 4 — Caregiver Onboarding

1. New caregiver submits an application (via WhatsApp link or website form), or admin adds them manually.

2. Application enters the **Onboarding queue**, status "Pending."
3. Admin reviews details and documents.
4. Admin approves → caregiver status becomes "Active," now visible in the booking-matching pool (Workflow 3). Admin rejects → status "Rejected," caregiver notified.
5. Audit log entry created for the decision.

Workflow 5 — Service Completion & Payment (Demo)

1. Caregiver (or admin on their behalf) marks the booking "Service Completed."
2. System generates the payment screen/link for the booking amount.
3. Link is sent to patient via WhatsApp, or patient pays caregiver directly.
4. Admin marks booking as "Paid" (via link simulation or "Paid — Collected Directly").
5. Revenue figures on the dashboard update; audit log entry created.

Workflow 6 — Admin/Management Dashboard Review

1. Admin or management logs in and opens the Dashboard.
2. Views bookings by status, revenue by period, caregiver availability, onboarding pipeline, and request source breakdown.
3. Optionally exports a report for a given date range.

Workflow 7 — Audit Trail Lookup

1. Management or admin opens the Audit Trail.
2. Filters by date range, actor, action type, or specific booking/caregiver/patient record.
3. Reviews the chronological, read-only log of actions for accountability or dispute resolution.

Non-Functional Notes & Demo Boundaries

- **Roles:** Admin (full operational access) and Management/Owner (dashboard + audit, read-mostly).
- **Data captured** should be enough to support the dashboard metrics and audit trail from day one, even in the demo build.
- **Out of scope for the demo:** live payment gateway, patient/caregiver-facing mobile app (this spec assumes admin-operated system + WhatsApp/website as the only patient/caregiver touchpoints), multi-language support (unless required).

- **Environment & setup:** hosting/environment, WhatsApp Business API provider (Meta direct vs. a BSP), and whether the website is custom-built or on a CMS (affects how the request form and WhatsApp button are embedded).
